What does data quality mean? Defining data quality in the organising of a global identification infrastructure for legal entities

Abstract

The vast amounts of data generated as a result of the growing digitisation of all aspects of contemporary life underpins a growing interest among practitioners and academics regarding how this mass of data can be utilised to enhance planning, strategizing, decision-making, sense-making, and other forms of cognition through data-driven business analytics and intelligence solutions. Realising this potential, however, is not straightforward and requires much sociotechnical work in order to make the data useable and useful for such solutions. We analyse how data can be made useable, useful, and therefore valuable through a study of the development and implementation of the Global Legal Entity Identifier System (GLEIS) as a case of establishing an infrastructure that certifies the accuracy and validity of identification data for corporate entities involved in financial markets transactions. Our findings describe a process whereby an identification infrastructure - including a non-replicable methodology for assessing data quality - is established that contributes to making the developer and controller of that methodology an irreplaceable intermediary for users of the infrastructure; this in spite of the need for an associated reference data infrastructure to be open and widely accessible to all participants in order for the infrastructure to be successful. The findings indicate that in the process assets are created out of openly-accessible data through the certifying of a desired set of qualities to be achieved by adopters and the infrastructure.

Keywords

Big Data, Data quality, Data capitalisation, Identification Infrastructures, Financial regulation

Introduction

The recent explosion of digital data across nearly all industries has created several opportunities for decision-makers to extract intelligence from data and translate it into business advantage (Brynjolfsson, Hitt, & Kim, 2011; McAfee, Brynjolfsson, Davenport, Patil, & Barton, 2012). The increased variety and speed of data creation, stemming from the growing digitisation of all aspects of economic life, has provided many opportunities for practitioners as well as regulators to plan, strategize, improve decision-making and enrich sense-making through so-called 'big data' business analytics and intelligence solutions (Chen, Chiang, & Storey, 2012; Glaeser, Kominers, Luca, & Naik, 2018; Günther, Mehrizi, Huysman, & Feldberg, 2017; LaValle, Lesser, Shockley, Hopkins, & Kruschwitz, 2011; Liu, 2014; Obermeyer & Emanuel, 2016; Phillips-Wren & Hoskisson, 2015; Warren Jr, Moffitt, & Byrnes, 2015; Zhang, Yang, & Appelbaum, 2015). These developments are of particular importance in information-based industries, such as financial services, where the calculation or risk, processing of payments, clearing and settlement of transactions, and overall provision of services relies on data-intensive and infrastructure-based processes. In this context, the ability to acquire, maintain, and analyse data is regarded as a key competitive factor, but also

1
2
3
4
5
6
7
8
9 as an attractive proposition for regulators to exercise effective supervision and ensure
10
11 market stability.
12
13

14
15 Early studies around the development of 'big data' were mostly driven by the idea that
16
17 what cannot be measured cannot be managed and thus, focused largely on the
18
19 usefulness of data to help manage businesses (McAfee et al., 2012) and bring strategic
20
21 advantages to firms (Brynjolfsson et al., 2011; Harris & Davenport, 2007). Further work
22
23 examined the effectiveness of analytical methods and their application and impact in
24
25 various business cases and sectors.
26
27
28
29

30
31 In spite of the recognition in the literature about the centrality of data to
32
33 organisations, there seems to be a lack of attention to the dynamics involved in
34
35 managing large and varied datasets. In particular, data quality and its validity as a basis
36
37 for organisational decision-making have until very recently remained unexplored apart
38
39 from a few notable exceptions (Park, Huh, Oh, & Han, 2012). This relative gap in our
40
41 conceptual understanding of data quality in organisations (Fox, Levitin, & Redman,
42
43 1994; Nagle, Redman, & Sammon, 2017; Redman, 1995, 2013, 2016) is becoming even
44
45 more crucial in light of recent developments relating to the integrity and use of data in
46
47 relation to social media and other such platforms (Rubin & Lukoianova, 2013; Zeng,
48
49 Chen, Lusch, & Li, 2010), as for example with 'fake news' on Facebook, 'engineered'

12
13

14
15 Data quality is of crucial importance in the context of financial data. For example,
16
17 when it comes to processes such as customer on-boarding, know-your-customer (KYC),
18
19 and other functions that involve the initiation or settlement of a transaction or credit
20
21 service. In such cases, organisational decision-making relies critically on the details of
22
23 the counterparties being correct, full, and up-to-date. On such occasions, customer
24
25 identification and/or authentication is pivotal and rests on the assumption that the
26
27 reference data and identification information held by those institutions involved in the
28
29 transaction cycle are valid and reliable. Inaccurate, erroneous, and missing data can
30
31 lead to suboptimal and costly situations resulting from the failure of transactions, the
32
33 miscalculating of risks, or from not complying with regulatory requirements. This
34
35 highlights the importance in such a context of information infrastructures that can
36
37 ensure a high level of identification reference data veracity in order to guarantee the
38
39 accurate and incontestable identification of market participants.
40
41
42
43
44
45
46
47

48 In this article we examine efforts to establish such an information infrastructure
49
50 through a regulatory initiative for identifying organisational entities that undertake
51
52 trading activity in financial markets. We regard this initiative as an attempt to establish
53

9 an identification infrastructure (Camp, 2004; Clarke, 1994; Eriksson & Agerfalk, 2010;
10 Whitley, Gal, & Kjaergaard, 2014), utilising a standardised global identifier for legal
11 entities (LEI) and, as part of this infrastructure, establish a set of organisational and
12 inter-organisational arrangements aimed at ensuring the reliability and veracity of
13 identification data. We examine empirically how processes aimed at ensuring data-
14 quality were developed as part of the establishment of the Global Legal Entity System
15 (GLEIS). We relate these processes to the concept of data *veracity* in the literature on
16 'Big Data' (Abbasi, Sarker, & Chiang, 2016; IBM, 2012; Rubin & Lukoianova, 2013). We
17 analyse the emergence of the LEI through the lens of data quality, a concept closely
18 related to Big Data's data veracity. Our analysis challenges the widely held assumption
19 in the Big Data literature that data veracity is conditioned on achieving certain degree
20 of technical proficiency organisationally. Instead, we propose that data quality is an
21 outcome of a broader sociotechnical process that we refer to as the development of
22 identification infrastructures. Importantly, our analysis indicates that data quality is
23 not a one-off achievement, but a dynamic and contested process in which many
24 different views among infrastructure participants have to be reconciled and inscribed
25 into the technical aspects of the infrastructure. Additionally, our case teaches us how
26 high data quality, as part of an identification infrastructure, enables the transformation
27 of data into a valuable commodity.

4
5
6
7
8
9 Our empirical examination focuses on how the infrastructure for data quality is
10
11 constructed as it reconciles the views of two differing groups of actors with regards to
12
13 the nature of data quality: the regulators and the users. Our examination indicates that
14
15 the viability and stability of this infrastructure depends on maintaining an effective
16
17 dynamic reconciliation between the two groups of actors. This empirical examination
18
19 also addresses wider interest in the big data and analytics literature (Abbasi et al.,
20
21 2016; Agarwal & Dhar, 2014). While this literature highlights the importance of having
22
23 data quality and data veracity, it tells us relatively little about how this is to be
24
25 achieved and maintained in practice. Our examination addresses this gap in the
26
27 literature. Building on this, our findings also help to shed light on the dynamics of ‘data
28
29 capitalisation’ - the processes through which the value of data is captured and realised
30
31 in terms of future economic gains and what is the role of information infrastructures in
32
33 this context (Abbasi et al., 2016; Doganova & Muniesa, 2015; Langley & Leyshon, 2017;
34
35 Najjar & Kettinger, 2013; Thrift & Leyshon, 2007). Our findings indicate that to
36
37 capitalise big and varied datasets (i.e. turn them into valuable assets), trust must be
38
39 obtained, but also actively maintained, in relation to the accuracy and relevance of the
40
41 data. Whilst the current literature merely notes the importance of such trust, our
42
43 research documents empirically the conditions necessary for establishing such trust
44
45 and the dynamics accompanying this process.

Background to the establishment of the GLEIS

To understand the motivations for the development of the LEI, we must return to the immediate aftermath of the global financial crisis of 2008. The collapse of Lehman Brothers in 2008 revealed a significant blind spot in the ability of financial regulators to foresee the concentration of liabilities that were accumulated via subsidiaries of global and systemically important financial entities. In particular, the absence of a standardised identification scheme prevented regulators from being able to determine who are the ultimate owners and/or controllers of financial obligations (Fleming & Sarkar, 2014; Jenkinson & Leonova, 2013; Lai & Mordel, 2012). This blind spot, in turn, highlighted a broader problem: the inability to trace how legal entities are first, identified, and secondly, relate to one another. This realisation called for a way to identify the legal entities and, as a corollary, to ensure the quality of the reference data describing these entities. For example, maintaining high quality identification data called for eliminating duplications resulting from the use of many variants or spellings of a company name and a plethora of different identifiers used for the same entities in relation to different activities in which they were engaged (e.g. FDIC Certificate ID, SEC CIK SWIFT ID, and various systems vendor proprietary IDs).

1
2
3
4
5
6
7
8
9 Regulators decided to address this problem through the instigation of a new market-
10 wide and cross jurisdictional identification infrastructure aimed at developing a
11 universal identification schema for legal entities engaged in any kind of financial
12 markets transactions across asset classes and trading venues. (Financial Stability Board,
13 2012; Legal Entity Identifier Regulatory Oversight Committee, 2015). At the core of the
14 infrastructure is a standard identifier format (International Standards Organisation,
15 2012; Legal Entity Identifier Regulatory Oversight Committee, 2015) and a mandating
16 of the use of the identifier in the reporting of financial markets transactions (Legal
17 Entity Identifier Regulatory Oversight Committee, 2015). From a data perspective, the
18 LEI links basic business data items (referred to as Level 1 or '*who is who*' data) with
19 identifying details of the legal entities. Later (as of May 2017) this link also included
20 Level 2 ('*who owns whom*') data about the ultimate and immediate owner of the
21 entity.
22

8
9 data and an issuance fee which is charged by the LOUs on a cost-recovery basis but
10
11 which can vary between LOUs according to their costs. Coordinating the operation of
12
13 LOUs was assigned to the Global Legal Entity Foundation (GLEIF), a not-for-profit
14
15 organisation. There are no restrictions as to who can become an LOU, but there are
16
17 clear requirements as to how LOUs can operate which are set out in a Master
18
19 Agreement between the GLEIF and the LOUs. GLEIF oversees the issuing and validating
20
21 of LEI identifiers but also the overall operation of GLEIS.
22
23
24
25
26

27 At the very top of the governance structure of GLEIS is the Regulatory Oversight
28
29 Committee (ROC) on which representatives of the financial markets regulators from
30
31 around the world sit and which oversees the work of the GLEIF and provides direction
32
33 as to the development and running of the GLEIS and the way the GLEIS is integrated
34
35 with the existing and future regulations it is associated with. This infrastructure for the
36
37 creation and maintenance of legal entity identification is referred to collectively as the
38
39 Global Legal Entity Identifier System (GLEIS).

Theory and development of research questions

In the big data and data analytics literature, data-quality is increasingly recognised as an important dimension for datasets that can underpin big data initiatives, with recent attention focusing on the *veracity* of data. Data veracity is defined as ‘the level of reliability associated with certain types of data’ including]truthfulness, accuracy or precision, correctness’ (Rubin & Lukoianova, 2013, p. 7). Data veracity, in turn, relates to the credibility assigned to the data, which is a function, in turn, of the trust the data source has with regards to a potential user of such data (Rubin & Lukoianova, 2013). In the context of identification data, such credibility relates not only to the data itself, but also to the perceived quality of the sociotechnical arrangements responsible for producing and maintaining the data. For example, identification data can suffer from semantic inconsistencies, lack of structure, conflicting evidence, multiple entries, and inaccuracies (Zeng et al., 2010). Many of these issues can be exacerbated when the data held by the infrastructure are user-generated (Zeng et al., 2010) and in such a context, ensuring high veracity of data sources can be a major challenge (Abbasi et al., 2016).

Identification infrastructures (IDIs) are a specific type of information infrastructures (Ciborra & Hanseth, 1998; Constantinides & Barrett, 2005, 2014; Hanseth & Braa,

1
2
3
4
5
6
7
8
9 2000; Hanseth, Monteiro, & Hatling, 1996; Monteiro & Hanseth, 1996) with the
10
11 specific aim of establishing a recognised identification of a particular actor, such as - in
12
13 this case - a legal entity, by associating them with a set of specific characteristics
14
15 (Beynon-Davies, 2016; Eriksson & Agerfalk, 2010; Otjacques, Hitzelberger, & Feltz,
16
17 2007; Whitley et al., 2014). These typically incorporate a unique identifier that is
18
19 matched to a reference dataset and in doing so helps to establish a link between an
20
21 entity's long-lived temporal attributes and the various occasions and contexts in which
22
23 the entity is involved (e.g. financial transactions with other entities) (Beynon-Davies,
24
25 2016; Eriksson & Agerfalk, 2010; Otjacques et al., 2007; Whitley et al., 2014).

26
27
28
29
30
31
32 The credibility and usefulness of an identification infrastructure (IDI) depends on the
33
34 quality of the identification data that underpin its operation and this will affect the
35
36 value this identification infrastructure provides to the entire ecosystem of users and
37
38 systems that utilise it. This is particularly important when an identification
39
40 infrastructure is highly embedded and linked to other infrastructures and practices.
41
42 Consequently, maintaining high veracity can be seen as a cost that needs to be
43
44 accounted for when evaluating the effectiveness and overall benefits (or return-on-
45
46 investment) of the infrastructure (Abbasi et al., 2016).
47
48
49
50

52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 Following the arguments above, we suggest that to arrive at a working identification
10 infrastructure, a process needs to be established that maintains the quality of the
11 reference data held by the infrastructure and identify what elements of data-quality
12 issues are more important to address. Thus, the establishment of an infrastructure for
13 reference data, such as identification data, calls for intermediated exertion of
14 influence between two or more actors through the development of domain-wide rules
15 that govern how references are to be associated with identification items and how
16 high veracity of data can be ensured. We suggest that the success of the GLEIS project
17 as an identification infrastructure should be examined through the achievement of this
18 goal.
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34

35 In turn, achieving such success depends on a high level of trust in the validity and
36 reliability of the identification data included in the GLEIS by the various actors with a
37 stake in the infrastructure. As such, we propose that it is vital to examine the
38 dynamics that evolved between the different stakeholders involved in the
39 development of the GLEIS identification infrastructure (regulators, policy makers,
40 infrastructure sponsors and operators, and market participants) around different views
41 they hold regarding data quality and how these different ways in which data quality
42 was viewed and understood were reconciled and incorporated into the technical and
43
44
45
46
47
48
49
50
51
52
53
54

56
57
58
59
60

1
2
3
4
5
6
7
8
9 organisational arrangements that form the GLEIS identification infrastructure. The way
10 this was done in practice during the development of the GLEIS highlights the central
11 importance of data and data quality in creating value for an identification
12 infrastructure such as GLEIS (Abbasi et al. 2016).
13
14
15
16
17
18
19

20 From the above discussion about the importance of data quality to big data initiatives
21 and the need for veracity to complement accepted data quality dimensions such as
22 data volume, variety, and velocity, three key questions emerge:
23
24
25
26
27
28

- 29 1. How are data quality – and in particular data veracity – achieved in practice in an
30 identification infrastructure that underpins a ‘big data’ initiative to regulate
31 financial markets around the world?
32
33
- 34 2. How is an intersubjective understanding of what constitutes data quality achieved
35 in practice and how does that condition the attitudes of infrastructure participants
36 towards the infrastructure?
37
38
- 39 3. How do processes intended to ensure and maintain data quality in the GLEIS IDI
40 relate to the capitalisation of data and making the resulting identification
41 infrastructure valuable through greater adoption and the generating of network
42 effects?
43
44

Research methods

Data collection

The main forms of data collected for the research were interviews and the documentation relating to the establishment of the Global Legal Entity Identifier System (GLEIS) from the sponsors of the GLEIF identification infrastructure such as the Regulatory Oversight Committee (ROC), the Commodities and Futures Trading Commission (CFTC), the Securities and Exchanges Commission (SEC), the Financial Stability Board (FSB), the G20, and the Global Legal Entity Identifier Foundation (GLEIF).

The aim in relation to the interviews was to speak to key individuals of relevance to the adoption of the LEI and/or establishment of the GLEIS from at least one organisation per stakeholder group. The duration of the interviews was between 35 minutes and 2 hours and aimed to gain an in-depth understanding of the workings of the GLEIS from the perspective of the interviewees and their organisations, in particular how the adoption of the LEI impacted the operations they were responsible for.

1
2
3
4
5
6
7
8
9 Overall, 32 individuals were interviewed in interview sessions totalling just under 38
10 hours and 36 documents relating to the establishment of the GLEIS and the
11 development of a data quality assurance process by GLEIF read. Figure 1 provides a
12 breakdown of the data collection by infrastructure participant groups.

22
23 Interviews and documents content were coded in terms of key controversies/points of
24 contention (Marres, 2004; Panourgias, 2015) using the NVivo software package as well
25 as by type of IDI participant group in order to arrive at a taxonomy of infrastructure
26 participants.
27
28
29
30
31
32
33

34 While a number of issues were identified through the first coding, through a second
35 coding, first order coding was consolidated into a few overarching categories
36 comprising of hierarchies of lower level coding clusters. This way it was possible to
37 classify the various top-level controversies in terms of their relative importance
38 according to the number of codes that comprised them, the depth of associated lower
39 level codes that comprised them, and the extent to which a controversy spanned the
40 entire set of IDI participant groups.

24 **Empirical account**

25 *Data quality processes in the GLEIS*

26
27
28 Through a combination of interviews from LOUs and the GLEIF, relevant documents,
29 and participant observation of the work done at an LOU in relation to the checking of
30 applicant data against authoritative sources, the following description of the processes
31 through which the quality of data in the GLEIS is assured was assembled (Langley,
32 1999).
33
34
35
36
37
38
39
40
41
42
43

44 The LEI issuing process (Figure 2) provides the first step in turning basic business data
45 into LEI data. The applicant entity provides its legal name, legal form, address and
46 corporate register to the LOU and this data is then checked by operatives at the LOU
47 against at least one local authoritative source, usually the relevant business register of
48 the applicant entity's jurisdiction.
49
50
51
52

7
8
9 [Figure 2 about here]
10
11
12
13
14
15

16
17 Once the quality of the data provided by the applicant has been checked by the LOU,
18 an LEI is issued. From that point onwards, it is the responsibility of the registering
19 entity and the LOU to ensure that the details of the identification data remain current.
20
21 The LOU may do so of its own accord, as part of its mandatory periodical checks or it
22 can be aided in this process by a challenge process (illustrated in Figure 3) whereby a
23 challenger can use the GLEIF web site to report on an erroneous piece of data.
24
25 Following this, the LOU is obliged to investigate the case and amend the data if
26 necessary.
27
28

43
44
45
46
47
48
49

50 Both elements of the data quality assurance process described above depend on a
51 chain of relations between the legal entity applying for an LEI, the LOU issuing the LEI,
52
53
54
55
56
57
58
59
60

9 and the GLEIF that oversees the LEI IDI and ensures the adherence of the LOUs to the
10 terms and conditions of their master agreement and subsequent service level
11 agreements with the GLEIS for the provision of LEI issuing services. These relations are
12 illustrated in Figure 4 and are a key aspect of the process through which the usefulness
13 and value of the LEI data is increased but also made dependent on the GLEIF and its
14 view of quality.

28

29 [Figure 4 about here]
30
31
32
33
34
35
36

37 A key element in this regime is the way that data quality itself is defined. Across the
38 different groups of infrastructure participants interviewed there were very differing
39 views of what constituted 'data quality', how this quality may or may not be measured,
40 and what implications any lack of quality – as they understood it – might have for the
41 use and adoption of the GLEIS IDI. It was, therefore, a key strategic move on the side of
42 the GLEIF to develop and put in place a methodology for assessing data quality into
43 which a particular view and definition of data quality was inscribed.

2
3
4
5
6
7
8
9 Quality of data in the approach put in place by GLEIF is measured and then certified
10 through an assessment of the data associated with the issued LEIs in terms of the
11 conformance of this data with set of Data Quality Criteria (see Table 1).
12
13
14
15

19
20

21 [Table 1 about here]
22
23
24
25
26
27
28

29 Underpinning each of these criteria are numerous checks (more than 200 and growing)
30 that measure the data in different ways (qualitative and quantitative) according to
31 these criteria. Each of the quality criteria can have a number of checks associated with
32 them. Furthermore, some of the checks are relational, where a certain check is
33 performed if another check has a certain value. The outcomes of these checks are then
34 aggregated and used to arrive at a quality score for the entire LEI dataset but also the
35 subset of the data according to the LOU it was issued by. Any failure of check is
36 recorded. It is through this process that each iteration of the LEI dataset is certified as
37 being of a certain quality according to the definition assembled by GLEIF. The resulting
38 data quality scores for both the entire LEI dataset, but also the data generated by the
39 various LOUs, is published monthly on GLEIF's website.

14
15
16
17
18
19
20

21 GLEIF's service-level agreements operationalise its definition of data quality. The
22 incorporation of the measurement methodology into the operational governance of
23 data quality influence the activities of other IDI participants and the sponsors and
24 participants of adjacent infrastructures that may provide inputs to, or use aspects of,
25 the GLEIS IDI.
26
27
28
29
30
31
32

33
34 This operationalisation aims to position GLEIF as the arbiter of the performance of the
35 LOUs, and, more broadly, as a critical hub in the overall identification infrastructure.
36
37 Firstly, the agreements between the LOUs and GLEIF make LOUs responsible for the
38 data quality of both the LEI applicants (that is, in terms of maintaining their own
39 identification data) but also, indirectly, of the authoritative sources used to verify the
40 data. This way, the influence of the GLEIF starts to extend beyond its own immediate
41 IDI and reaches throughout the entire identification infrastructure and beyond. For
42 example, the service-level agreements are used to incentivise the LOUs to apply
43 pressure on national business registers to improve the quality of their data which is
44
45
46

2
3
4
5
6
7
8
9 use to check the correctness of legal entity data when it is submitted as part of a
10
11 request for an LEI number.
12
13

14
15 Furthermore, the combination of agreements and methodology also enables the GLEIF
16
17 to provide a degree of intervention into the operations of the LOUs by providing them
18
19 guidance through relationship managers as to how recurring types of data quality
20
21 problems (e.g. see 'Top 5 Failing Checks' in Figure 5) can be rectified through process
22
23 and policy change recommendations which can be made very 'hard' through a possible
24
25 revocation of the authorisation to issue LEIs. In fact, through forward-looking
26
27 dimensions of the data quality measures (e.g. 'Quality Maturity Level' in Figure 5), the
28
29 agreement-based relationship between GLEIF and LOUs even directs future action of
30
31 the LOUs towards attaining higher data quality criteria. For example, setting up a very
32
33 high goal that needs a continuous striving and improvement to attain, is conducive to
34
35 GLEIF maintain themselves as the arbiter of data quality. This configuration of data
36
37 quality is also aligned with the possible goal of maintaining GLEIF as an obligatory point
38
39 of passage (Callon, 1984; Latour, 1987) in the nascent IDI.
40
41
42
43
44
45
46
47

48 *Competing views on data quality*

49

50
51 Overall, the analysis generated 15 high-level codes consolidating 118 lower level codes
52
53 representing a total of 218 coding points. Of these, 39 of the lower level codes (45
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 coding points) related to the overall high-level category of 'Data' and of these, 31 (41
10 coding points) related to the sub-category of 'Data quality'. The top issues within the
11 'Data quality' category related to 1) the inclusion of Level 2 ownership data, their
12 compilation, and the implications this would have for IDI participants and 2) the
13 maintenance and validity of LEI data.
14
15
16
17
18
19
20
21

22 Taken across the 'Data quality' subcategory, our empirical examination of these
23 codings and the underlying coding points indicates that across the different groups of
24 actors involved in the identification infrastructure there were very differing views of
25 what constituted 'data quality', and what implications any lack of quality may have.
26
27
28
29
30
31
32
33

34 As described in the previous section, quality of data in the methodology that GLEIF
35 developed is measured and then certified in a process whereby the data is examined
36 through assessing its conformance with an array of descriptors, known as Data Quality
37 Criteria, aimed at capturing different dimensions of quality (see Table 1). This view of
38 data quality is informed by an engineering/manufacturing approach to 'quality' along
39 the lines of the Total Quality Management, whereby the ultimate aim is to produce
40 and maintain high data quality that strives for zero errors across the entire dataset.
41
42
43
44
45
46
47
48
49
50
51 This view can be understood as a process-oriented view towards data quality. In
52 essence, GLEIF's concept of data quality regards it as an indication of the suitability of
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 organisational structures and practices associated with the assembling of the
10
11 identification data and, following this view, aims to create a trusted infrastructure for
12
13 data quality; a structure that generates and guarantees reliance on the infrastructure.
14
15

16
17
18 On the other hand, financial service providers, such as investment banks, who are both
19
20 users and producers of the identification data but may also act as intermediaries for
21
22 the LEI needs of their clients, regard data quality from a commercial perspective. In
23
24 particular, the service providers focus primarily on the sections of the identification
25
26 data that their commercial experience indicates are likely to be of high demand and
27
28 point their resource towards ensuring that this data remains of high quality. As a
29
30 result, less attention is paid to the rest of the data, whose quality deteriorates over
31
32 time, as it is not updated and verified.
33
34
35
36
37
38

39 The focus on data quality through the prism of revenue generation also affected
40
41 another element in relation to how LEIs are treated – as a way to reduce operational
42
43 costs. A typical comment from our interviewees follows:
44
45
46
47

48 Operationally, the creation and maintenance of a universal identifier for companies'
49
50 names is going to simplify and reduce the cost of maintaining identifiers [because] in
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 order to create cross platform compatibility, they need to rely on fuzzy matching,
10
11 which is expensive, not accurate and time consuming.
12
13

14
15 Interviewees regarded LEIs as a viable solution to the situation where multiple
16
17 identifiers existed both within their organisation and across organisations. In such a
18
19 scenario the adoption of the LEI would be of benefit, but its viability relies on
20
21 maintaining a high quality of data across all identification items, which is a costly
22
23 process with uncertain revenues. Given this difficulty, interviewees regarded the
24
25 maintenance of high -quality LEIs primarily as a regulatory requirement and,
26
27 consequently, focused on the costs it may save once in place, rather than as an
28
29 opportunity to generate revenues.
30
31
32
33
34

35
36 In particular, when envisioning the operational environment of LEIs, many of our
37
38 interviewees preferred to talk about the goals of the LEI system once these goals were
39
40 achieved, but noticeably leave out of the discussion how these would come about. For
41
42 example, interviewees repeatedly mentioned how beneficial it would be for their
43
44 organisations when there is a common language in place for the identification of
45
46 entities, but when asked about what their organisation can do to help bring about this
47
48 desired outcome, many interviewees indicate that this is a regulatory challenge and, as
49
50 such, it cannot be the task of any single organisation to realise this outcome.
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 Another important area where differences regarding the conceptualisation of data
10 quality are revealed concerns the motivations of the actors involved in operationalising
11 data quality. A difficulty that many of our interviewees envisioned related to the fact
12 that financial institutions typically provide trade execution services to their customers,
13 which makes the customers in need of LEI registration. Such situations would leave the
14 service providers, if they register their customers to the LEI system, responsible for the
15 accuracy and validity of the identification details of, potentially, thousands of trading
16 entities, many of which may terminate, as time passes, their commercial relations with
17 the service providers. This potential obligation was one that virtually none of our
18 interviewees from service-providing financial institutions wished to undertake, as this
19 was seen as 'bottomless pit' of legal and operational burdens. Furthermore, there
20 were also worries about providing third parties (their current clients) with 'a licence to
21 trade' and all the implications this carries in terms of reputational and regulatory risks
22 for them from these clients and their activities.
23
24
25
26
27
28
29

31
32
33
34
35
36
37
38
39
40
41
42
43

44 In summary, GLEIF focuses its design and enforcement efforts on the LOUs, which are
45 rewarded for auditing the quality of identification information. These show that
46 discrepancy between how the regulators see the implementation of LEIs and how
47 financial institutions see the exact set of activities. While the regulators focus on data
48
49
50
51

2
3
4
5
6
7
8
9 quality from the perspective of the LOUs, which are focused primarily on registering
10 LEIs and assuring data quality, the end users view the LEI process as an auxiliary of
11 their financial service provision, but one that generates no revenue and carries with it
12 the imminent possibility of significant costs.
13
14
15
16
17
18
19

20 *GLEIF: from identifier developer to data quality certifier*

21
22
23 While studying the development of the GLEIS in conjunction with the unfolding of the
24 'data quality' controversy, another aspect of 'data quality' surfaced. This was that the
25 development and adoption of an intersubjective way to define and measure data
26 quality within the GLEIS started to have effects beyond the confines of the GLEIS IDI.
27
28 The definition and measurement of data quality within the GLEIS helped make the
29 GLEIF view of data quality and its assessment an industry yardstick against which the
30 data quality of other existing financial and regulatory IDIs can be assessed. In the face
31 of a lack of alternative definitions and quality assurance methodologies in these
32 related IDIs, GLEIF's definitions and methods are being used to assess data quality in
33 other IDIs where legal entity identification is central (e.g. Business Identification Codes
34 (BICs) in the banking industry and legal entity identification associated in relation to
35 the Foreign Account Tax Compliance Act (FATCA) in the United States).

8
9 Looking at the evolution of GLEIF as an institution in parallel to the putting in place of
10 the data quality assurance criteria and processes for the GLEIS, the role of GLEIF has
11 been changing, from one of overseeing the operation of the GLEIS identification
12 infrastructure to one of becoming a wider arbiter of data quality for entity
13 identification in other financial and accounting infrastructures.

34 **Discussion**

35 *Veracity and the dimensions of data quality*

36
37
38 Our empirical account reveals significant differences between the way data quality is
39 defined in the context of the GLEIS, and the way data quality is discussed in the
40 existing big data literature (Abbasi et al., 2016; Rubin & Lukoianova, 2013). In relation
41 to data quality and its definition in the area of 'big data', we argue, drawing from on
42 our empirical findings, that the meaning of 'data quality' is situated in the use-context
43 of the 'big data' initiative examined, raising questions about the applicability of pre-
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 determined dimensions of data quality, such as the 4Vs (Abbasi et al., 2016; Rubin &
10 Lukoianova, 2013). We find that data quality and its definition and measurement is
11 drawn from the use contexts which reflect the concerns and interests of stakeholders
12 and, as such does not fit the ‘top-down’ approach implied in the Big Data literature.
13
14 While the notion of dimensions of quality is there in the empirical case, those
15
16 dimensions are more specific to the context of the GLEIS and the concerns and
17
18 interests of the various infrastructure participants. Rather than the 4Vs of velocity,
19
20 variety, volume, and veracity (Abbasi et al., 2016; Rubin & Lukoianova, 2013), three
21
22 high-level ‘characteristics’ of *openness* (data being accessible to everyone), *reliability*
23
24 (GLEIS data comparing favourably to other existing standards), and *trust* (continuous
25
26 improvement of the data quality), were defined by the GLEIF. These three high-level
27
28 characteristics were then broken down into 12 quality criteria (see Table 1) and then
29
30 more than 200 checks used to measure data quality and compare the performance, in
31
32 terms of data quality, of LOUs but also of the GLEIS as a whole.
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47

48 *Giving meaning to ‘data quality’*

49
50
51 It is a key finding from our empirical study that data quality is a dynamic on-going
52
53 sociotechnical achievement that reflects the concerns and interests of stakeholders
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 touched by the data rather than a stable final state. It is therefore crucial to
10
11 understand how an intersubjective understanding of the meaning of 'data quality' is
12
13 arrived at and what implications this has for the attitudes those touched by this exhibit
14
15 towards the 'big data' solution developed.
16
17
18
19

20 To understand how such alignment of interests may come about, we refer again to
21
22 data veracity. Data veracity is related to the usefulness of the data in the organization.
23
24 Indeed, As Abbasi et al (2016) point out 'with organizations treating data as a primary
25
26 asset, assessing and, in some cases, quantifying the value of volume and variety
27
28 relative to the costs of veracity becomes of paramount importance to evaluate the
29
30 effectiveness of big data investments'. The case of GLEIS's data quality shows that in
31
32 the case of identification data, recognising the data items as valuable comes as a result
33
34 of multiple stakeholders aligning their incentives and thus facilitating the viability of
35
36 the infrastructure that maintains it in order to invest in infrastructures that would
37
38 maintain a high quality of data.
39
40
41
42
43
44
45

46 Maintaining such alignment among the actors is difficult, since the different actors
47
48 follow conflicting logics. We distinguish these as being the followers of either a
49
50 *commercial logic*, such as the financial service providers, in contrast to GLEIF, which
51
52 follows a *regulatory logic*. Actors that follow a commercial logic, as our case indicates,
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 wish to minimise costs in relation to data veracity if they cannot identify how increased
10 data quality would lead to economic benefits. Their focus is more on maintaining the
11 high quality of the parts of the data that are likely to generate revenue for them. As a
12 result, only a relatively small subset of the data would be maintained at high quality.
13
14
15
16
17
18

19
20 In contrast, actors who follow a *regulatory logic* in relation to identification data aim
21 for the overall data quality to increase so as to reduce the risk stemming from having
22 inaccurate data items. These two logics highlight the conflicting motivations and
23 divergent identification needs of different participants in an IDI and the different views
24 they have regarding identification data quality and how that quality should be
25 achieved and maintained.
26
27
28
29
30
31
32
33
34
35

36 In the case presented, we understand the decision of GLEIF to delegate the
37 maintenance of LEI data quality to LOUs as a way to alleviate the threat to the stability
38 of the IDI. GLEIF wished to associate data quality maintenance with actors who follow
39 a commercial logic, but ones whose commercial interests are aligned directly with the
40 maintenance of the entire corpus of identification data at a high quality, the LOUs. The
41 LOUs, in contrast with the end-users of the LEIs, expected to make financial gains from
42 providing verification and registration services to end users. The LOUs' ability to
43 generate revenues were dependent on the end users' trust in the quality of data.

2
3
4
5
6
7
8
9 Moreover, GLEIF's restrictive data quality regime and the fact that the LOUs cannot
10 know in advance which section of the identification data is likely to be more in
11 demand, motivated the LOUs to high quality data universally. GLEIF's definition of data
12 quality, once operationalised into the service-level agreements with the LOUs making
13 the latter responsible for the data quality of the LEIs, brought about an implicit
14 agreement about how data quality is to be maintained and contributed to an improved
15 stability of the IDI. In more generalised terms, we can argue, on the basis of our
16 findings, that GLEIF made itself an indispensable part of the infrastructure, what is
17 referred to as an 'obligatory point of passage' (Callon, 1984, 1987; Latour, 1987) by
18 framing the quality-related concerns of the various actors involved in IDI and inscribing
19 this framing into a techno-institutional data quality methodology.

35
36

37 *Processes of 'capitalisation through certification'*

38
39
40 From both the regulatory and commercial perspectives outlined above, the definition
41 of data quality through the GLEIF quality criteria (Table 1) and the putting in place of a
42 quality assurance process through which the performance of the LOUs is assessed and
43 managed have important future implications.
44
45
46
47
48
49
50

51 First, it provides a way of giving value to the basic business data owned by those being
52 identified through the new IDI. Even if substantially the same as the raw company
53
54
55
56
57
58
59
60

1
2
3
4
5
6
7
8
9 data, the entity data that is certified through the GLEIS is more valuable than the raw
10
11 company data outside the GLEIS. Furthermore, having in place the GLEIF quality
12
13 criteria and the GLEIF quality control process makes it possible for future regulators to
14
15 control the evolution of the infrastructure by adjusting the criteria and/or the quality
16
17 control and certification processes. Second, the definition and measurement of data
18
19 quality within the GLEIS also establishes a benchmark against which other IDIs in
20
21 adjacent areas of financial and regulatory activity can be assessed.
22
23
24
25
26

27
28 Given the current state where there is lack of alternative definitions and quality
29
30 assurance methodologies, GLEIF's definitions stand a good chance of becoming a more
31
32 widely adopted standard. The gap that exists in defining and assessing data quality in
33
34 other areas of financial and regulatory activity where regulators are seeking data-
35
36 driven approaches to regulation has enabled the direct or indirect linking of GLEIS with
37
38 other related informational infrastructures, increasing further the potential value of
39
40 both the GLEIS and of GLEIF-certified entity data. The development of a process of
41
42 'capitalisation by certification', therefore, not only gives usefulness and value to the
43
44 data of an IDI, but, in the absence of other such quality assurance processes in related
45
46 areas of identification, can generate potential network effects through an association
47
48 with other IDIs that do not have similar processes in place.

Conclusion

This article addresses the wider growing interest in the big data and analytics literature (Abbasi et al., 2016; Agarwal & Dhar, 2014) regarding how data quality can be defined and measured and how this relates to the dynamics of how data gains value (Langley & Leyshon, 2017; Thrift & Leyshon, 2007; Millo et al., 2019) and the processes through which the value of data is captured and realised (Doganova & Muniesa, 2015; Najjar & Kettinger, 2013). It relates this to the extensive literature in information systems research on information infrastructures (Ciborra & Hanseth, 1998; Constantinides & Barrett, 2005, 2014; Hanseth & Braa, 2000; Hanseth & Monteiro, 1997; Hanseth et al., 1996; Monteiro & Hanseth, 1996), and in particular identification infrastructures (Camp, 2004; Clarke, 1994; Eriksson & Agerfalk, 2010; Whitley et al., 2014). It also addresses the recent interest in both academic literature (Hu, Zhao, Hua, & Wong, 2012) and among practitioners (Davies, 2019; van Steenis, 2019) about the use of 'Big Data' in financial services regulation in what Davies (2019) refers to as 'regtech' solutions for the regulation of increasingly digitised and global financial activities.

Due to the way that 'big data' can touch on a multitude of stakeholders, both in terms of the use but also the generation of data, being in a position to define in an

1
2
3
4
5
6
7
8
9 intersubjective way what is meant by 'data quality' and how this is measured can
10
11 provide a degree of control to the promoters of a 'big data' initiative in terms of the
12
13 design and evolution of the initiative vis-à-vis the resistances and/or buy-in of affected
14
15 stakeholders. This is because good data quality that is recognised intersubjective as
16
17 such by those touched by it fosters network effects in terms of adoption and usage
18
19 that add value to both the data itself but also the infrastructures through which the
20
21 data in question is compiled and used.
22
23
24
25
26

27 All the points highlighted in this concluding section point towards certain
28
29 'infrastructural' aspects of 'big data' initiatives such as the one presented. This gives
30
31 new currency to the literature on infrastructures and infrastructures-making built on
32
33 the conceptualisations developed by Star (1999); (1996) and which can contribute
34
35 much to the study of phenomena such as Big Data (Kornberger et al., 2019). Along
36
37 these lines, the GLEIS case shows that organising financial regulation on a global scale
38
39 using data is likely to be as much about giving meaning to categories and concepts
40
41 such as 'data quality' and developing ways to measure and asses these as it is about
42
43 putting in place regulations mandating or prohibiting certain activities and practices.
44
45 Furthermore, such apparently small technicalities, once put in place, can spread,
46
47
48
49
50
51
52 having an influence on adjacent areas of activities with common date needs and uses.
53

56
57
58
59
60

1
2
3
4
5
6
7
8
9 This is particularly the case with IDIs, which can act as linkages between many diverse
10 datasets enabling cognition and action in many other areas beyond those for which the
11 IDI might have been developed for in the first place. It will be paying attention the
12 sociotechnical 'life' of data and studying data as such, instead of treating data as a
13 purely technical issue, that new data-driven ways of organising that are entering more
14 and more aspects of modern life can be understood and studied better.

Data Quality Criteria	Description
Accuracy	Data is free of identifiable errors and conforms with an authoritative source; Represents correctly real-world objects
Accessibility	Ease and legality of access
Completeness	All required occurrences are populated.
Comprehensiveness	All required data items are included and all possible scope of the data is collected
Consistency	Unique piece of data holds the same value across multiple data sets.
Currency	Data are up-to-date
Integrity	Conforms to defined data relationship rules
Provenance	Pedigree of a data property value
Representation	Fit of format of data to its intended use
Timeliness	Data is available when it is required.
Uniqueness	Distinct values of data elements appear only once.
Validity	Data value conforming to its domain value
