Is Panama really your tax haven? Secrecy jurisdictions and the countries they harm

Petr Janský, Markus Meinzer, Miroslav Palanský¹

Abstract

The Panama Papers underscored financial secrecy's role in the global economy. Yet, naturally, for most countries Panama is not the most harmful secrecy jurisdiction. In this paper we aim to quantify for each country which secrecy jurisdictions harm them most and whether countries are successful in targeting these jurisdictions with their policies. To that objective we develop the Bilateral Financial Secrecy Index and estimate it for 86 countries by quantifying the financial secrecy supplied to them by 112 secrecy jurisdictions. We find that the December 2017 European Commission's list includes only 11 out of 15 secrecy jurisdictions that are most harmful for the European Union. We also find that many countries worldwide are not successful in establishing automatic information exchange with their most important secrecy jurisdictions. Since countries are still being harmed by a variety of secrecy jurisdictions, Panama or others, more targeted policy efforts can diminish financial secrecy and thus the harm done.

Keywords: tax havens; secrecy jurisdictions; financial secrecy; financial transparency; offshore finance; automatic exchange of information; global development

JEL classification: F36, F63, F65, H26, O16

1 Introduction

Recent offshore leaks of confidential documents reaffirmed the global nature of financial secrecy in which many countries now serve as secrecy jurisdictions by providing financial secrecy to other countries. The Panama Papers, for example, affected the valuation of firms around the world (O'Donovan, Wagner, and Zeume 2016). Despite this global nature of the offshore world (Palan 2003), secrecy jurisdictions, or tax havens (terms that we use interchangeably throughout this paper), tend to specialize geographically and in the kinds of services they provide. Some focus more on low taxation for multinational enterprises (Alvarez-Martinez et al. 2018), while others offer high financial secrecy (Cobham, Janský, and Meinzer 2015). Furthermore, each tax haven is relevant for a different set of countries. For example, while Cyprus has been a favourite tax haven for Russia and combines both low taxation and high secrecy (Pelto, Vahtra, and Liuhto, 2004; Ledyeva et al. 2015), Mauritius has been notoriously secretive and important for multinational enterprises active in India (Janský & Prats, 2015; Schjelderup, 2015). Unlike these examples, systematic evidence of which secrecy jurisdictions are important for which countries has so far not been available, at least not for a large number of countries.

To fill this gap, in this paper we quantify which secrecy jurisdictions harm individual countries the most and whether countries are successful in targeting these secrecy jurisdictions with their policies. To that objective we develop the Bilateral Financial Secrecy Index (BFSI) on the basis of the Financial Secrecy Index (FSI) by Cobham, Janský, and Meinzer (2015). The BFSI is a direct country-specific extension of the FSI, and answers a similar, but somewhat more nuanced question than the FSI: Which jurisdictions contribute most to the financial secrecy to which each specific country is exposed? We estimate the BFSI for 86 countries with available data by quantifying the financial secrecy supplied to them by 112 secrecy jurisdictions. We use the BFSI to uncover the heterogeneity in the specialization of different secrecy jurisdictions and demonstrate its usefulness as a tool to evaluate policy responses. Two widely discussed policy measures in response to harmful financial secrecy are the European Union's blacklist of tax havens (European Commission 2017b) and automatic tax information exchange (AIE) (OECD 2015). We analyse the congruence between the jurisdictions on which these policy measures have focused and the jurisdictions which empirically supply most secrecy to any given country as revealed by the Bilateral Financial Secrecy Index. Such comparisons can, for example, reveal systematic inefficiencies in taming tax havens or, more practically, cases where policies should be redirected towards secrecy jurisdictions which supply most secrecy.

Determining which secrecy jurisdictions supply most financial secrecy to each country is a challenging task and systematic evidence of the economic relationships among individual countries and secrecy jurisdictions for a large number of countries is scarce for understandable reasons. First, empirical identification of tax havens' financial secrecy, which by design might not want to be identified, is difficult and even more so at the bilateral level. Second, and relatedly, due to tax havens' reluctance to be transparent, there is hardly any cross-country data about the economic scale of countries' relationships with some of the most secretive tax havens. Unsurprisingly then, the research question outlined above has so far remained largely without systematic responses. For the first time, we provide evidence on which secrecy jurisdictions are important for 86 individual countries.

To estimate which secrecy jurisdictions are most harmful for which countries we need both a measure of the intensity of financial secrecy of a jurisdiction and an indicator showing the strength of the economic relationship between each pair of jurisdictions. For the measure of the intensity of financial secrecy we use the secrecy scores of the 2018 Financial Secrecy Index, established as the leading, if not the only, indicator of financial secrecy (Cobham, Janský, and Meinzer 2015). The secrecy score is a qualitative indicator comparable across 112 jurisdictions (Tax Justice Network, 2018). Since these secrecy scores are published as a single indicator for each jurisdiction and thus without distinguishing between various partner countries, we need to make the assumption that financial secrecy does not differ with respect to the receiving country. While knowing this assumption is sometimes violated (e.g. when specific bilateral agreements such as AIE are in place), there is no comparable (or even more detailed, i.e. country pair-specific) indicator that we could use instead. As an indicator of the scale of the relationship between each country and secrecy jurisdiction, we use the International Monetary Fund's (IMF) data on total portfolio investments. This data fulfils the condition of being relevant for the provision of financial services that can be abused under conditions of secrecy, and are available for many relevant countries worldwide and on a bilateral basis. A combination of

these two information sources enables us to derive the BFSI as a country-specific ranking of the harm caused by individual secrecy jurisdictions. By aggregation in political, income, and geographical groups, the BFSI can be used to analyse the geography of financial secrecy by differentiating between the recipients and suppliers of financial secrecy. While the harm caused through financial secrecy is not directly observable, in this paper we consider suppliers of financial secrecy as those harming other jurisdictions on the basis of financial secrecy creating a criminogenic or enabling environment for illicit financial flows. Vice versa, we treat receivers of financial secrecy as those being harmed by secrecy jurisdictions.

As we show in this paper on the examples of tax haven blacklists and automatic information exchange, the BFSI is useful for evaluating the policymakers' efforts to fight financial secrecy. Automatically exchanging tax information between pairs of countries under the Common Reporting Standard is a relatively novel international policy response to harmful financial secrecy. Often regarded as an innovative policy for addressing cross-border tax evasion, the de facto exclusion of developing countries and a lack of incentives for large uncooperative countries to participate, the United States in particular, remain some of the challenges for AIE itself (Meinzer 2017). Yet the network of bilateral exchange relationships (over 2600 as of 21 December 2017) keeps growing since 2016, currently covering 78 countries (OECD 2018). The conventional wisdom in the literature expects tax havens to fight for excluding their most relevant secrecy counterparts from their information exchange network. Conversely, more powerful countries are expected to more successfully coerce tax havens to exchange information with them (Hakelberg and Schaub 2017). We test these hypotheses by checking how much of any country's BFSI is or is not currently covered by active AIE relationships. For policy makers, our findings provide guidance as to which secrecy jurisdictions they should make it their priority to activate AIE relationships with. Similarly, we analyse the coverage of the European Union's recent blacklists to see whether they are neatly pointing to the tax havens of highest importance for the European Union as a whole, or if the blacklisting exercise is driven by other, most importantly political, motives (Knobel and Meinzer 2015; Meinzer 2016).

Having developed and estimated the BFSI as a country-specific indicator of financial secrecy, we first confirm the findings of the FSI that some major global economies are responsible for the bulk of global harmful financial secrecy. For most countries, the United States, Switzerland, and Cayman Islands are among the most important secrecy jurisdictions. From the detailed results of the BFSI, we learn that certain countries are affected relatively more by specific secrecy jurisdictions, such as European economies by Luxembourg and the Netherlands, or the United States and Japan by the Cayman Islands. Generally, our results point to many countries supplying harmful secrecy and we argue that only extensive cooperation of countries at the global scale is capable of taming the bulk of harmful financial secrecy. Comparing the results of the BFSI for the European Union with the recent efforts of the EU to blacklist important tax havens, we find that only 11 of the top 15 contributors to financial secrecy in the EU have been identified by the Commission's screening process. At the same time, the blacklist includes jurisdictions which are very unlikely to be relevant suppliers of harmful secrecy.

Finally, we observe how big a share of harmful secrecy is covered by existing active AIE relationships. We find that countries have not been particularly successful so far at setting up AIE with tax havens that predominantly supply financial secrecy to them. On average, the EU member states have covered 78.5% of the received secrecy, while among lower-middle income countries, we document that only India and Indonesia have been actively signing AIE treaties and have covered around 72% of the secrecy they receive. Some other countries have not yet activated any AIE relationships. In terms of covering the supplied secrecy by AIE, we find evidence consistent with the notion that more secretive countries are aware of what the destinations of their secrecy are and successfully avoid setting up AIE with these jurisdictions. Our results thus point to AIE being of high importance to secrecy jurisdictions, and future policy efforts should stress the development of AIE relationships with the most secretive tax havens. We identify the secrecy jurisdictions that provide the most secrecy and have so far managed to avoid AIE treaties to be the United States, Taiwan, United Arab Emirates and, indeed, Panama.

This paper contributes, with a combination of these findings, conceptual arguments and methodology development, to three broad strands of economic literature. First, research on tax havens has been growing in recent years, yet lacks systematic bilateral analyses of financial secrecy. Most economic studies quantify the effect that low tax rates have on inward FDI or profit allocation of multinational corporations, with recent literature overviews provided by Dharmapala (2014) or Dowd, Landefeld, and Moore (2017). While most of

the papers such as Crivelli, de Mooij, and Keen (2016) and Cobham and Janský (2018) quantify tax revenue losses only aggregately for a group of tax havens, recent papers such as Cobham and Janský (2017) and Tørsløv, Wier, and Zucman (2017) manage to attribute the responsibility for the losses to specific tax havens. Similarly, Egger et al. (2009) account for bilateral aspects of taxation in their estimation of effective tax rates and find that relying only on unilateral rates leads to biased estimates. Yet, there is less empirical research on the impact of financial secrecy. For example, Johannesen & Larsen (2016) find that the introduction of country-by-country reporting of tax payments in extractive industries is associated with significant decreases in firm value, while Dyreng, Hoopes, & Wilde (2016) find evidence of the impact of public pressure on firms that fail to comply with a financial transparency rule. Another undercurrent of the tax haven literature focuses on the size of offshore wealth, for which Zucman (2013) and Henry (2012) provide global estimates and which has been enriched recently by Caruana-Galizia & Caruana-Galizia (2016) and Zucman, Johannesen, and Alstadsaeter (2017) by combining traditional data sources with data becoming available through the recent offshore leaks.

Much of this tax haven-related research has dealt with the definitional issues by differentiating groups of tax havens according to the type of taxation (Eden and Kudrle 2005), or on the basis of activity (AviYonah 2000; Kudrle and Eden 2003). Later, a “consensual approach” has been originally pioneered by Palan, Murphy, & Chavagneux (2009) and relabelled “expert agreement” by Haberly & Wójcik (2015b). This approach applies classifications of tax havens on the basis of a number of mentions on the lists of tax havens. An alternative approach has been developed by Garcia-Bernardo et al. (2017) with the use of firm-level data. The Financial Secrecy Index (Cobham, Janský, and Meinzer 2015) offers another approach at overcoming these definitional issues. Also, while the FSI pioneered the quantification of the term secrecy jurisdiction, this term was already in use a few decades ago, as documented by Peet & Dickson (1979) and the United States House of Representatives (1970). The FSI operationalised the concept of a secrecy jurisdiction by attributing each reviewed jurisdiction a secrecy score and combining this with the jurisdiction’s market share in offshore financial services. This approach allows accommodating all countries on a spectrum of secrecy and global secrecy contribution, rather than maintaining a somewhat arbitrary dichotomy between tax havens and other countries. With the FSI, some major secrecy-supplying economies come into focus in addition to the resource-poor micro-states considered by earlier literature (Hudson 2000; Roberts 1995). Similar to the papers referred to above which incorporate bilateral country pair analyses into corporate tax research, with the BFSI we add a new level of analyses to the original approach of the FSI.

The second strand of literature to which we contribute with the BFSI is that on illicit financial flows and (anti-) money laundering, most of which concerns definitional questions and measurement methodologies (Hong and Pak 2017, Reuter 2012, Kar and Cartwright-Smith 2009). Cobham (2014), however, used measures of financial secrecy from the FSI 2013 to identify country-specific vulnerabilities, and used other bilateral economic data, such as foreign direct investment and commodity trade, to rank vulnerabilities for a range of African countries. In this subcurrent of literature, both Schwarz (2011) and Gnutzmann, McCarthy, & Unger (2010) relate to tax havens and financial secrecy, arguing that poorer and smaller countries bear only a tiny share of the total costs relative to the potential benefits of investment that money laundering offers, and so have a higher incentive to tolerate the practice compared to their larger neighbours. More recently, economists in anti-money laundering increasingly use measures of financial secrecy as risk factors (Savona and Riccardi 2017; Cassetta et al. 2014). In this paper, we employ a similar approach to the one pioneered by Cobham (2014), yet focus on a specific type of bilateral economic data and carry out an analysis on a global scale.

Finally, the third strand of literature to which we contribute is the rapidly developing area of responsiveness of economic behaviour to exchange of tax information. In an influential paper that spurred this stream of research, Johannesen and Zucman (2014) assess the impact of G20 policy crackdown on tax havens and find that tax evaders tend to shift deposits to havens not covered by a treaty with their home country. Braun & Weichenrieder (2015) find evidence that the conclusion of a bilateral tax information exchange agreement is associated with fewer operations of German MNEs in those tax havens and therefore that these tax agreements affect FDI as well, which they consider as suggesting that firms seek out tax havens not only due to tax, but also because of secrecy they offer. Relatedly, Hanlon, Maydew, and Thornock (2015) examine a form of round-tripping tax evasion in which US individuals hide funds in entities located in offshore tax havens and then invest those funds in US securities markets. With the advent of automatic exchange of tax

information, new research has been started. Hakelberg and Schaub (2017) examined the case of the USA which successfully coerced smaller tax havens into an information exchange regime, while abstaining itself from participation. Miethe and Menkhoff (2017) analysed the effect automatic information exchange relationships have on banking deposits in tax havens and others. They found a similar effect to the one identified by Johannesen and Zucman (2014), that banking deposits fall upon the signing of a bilateral exchange agreement. Our contribution to this strand of literature consists in overlaying the bilateral financial secrecy configuration of any jurisdiction with its automatic exchange network. By doing so, we are able to contribute to both academic and policy relevant findings, e.g. on which secrecy jurisdictions might be missing from any country's treaty network, and where secrecy jurisdictions successfully refrain from engaging in exchanges.

The remainder of this paper is structured as follows. Section 2 introduces the data, while Section 3 explains the methodology. Section 4 discusses the results, especially the comparison of the BFSI with the current state of policies regarding tax haven blacklisting and automatic information exchange. Section 5 concludes.

2 Data

In this section we summarize the sources of data used in our empirical analysis: first, we describe the data that enter the estimation of the Bilateral Financial Secrecy Index; second, we present the sources of data on automatic exchange of information relationships and blacklists of tax havens. An important departure from the original FSI methodology is in the data that we use to estimate the quantitative part of the index. The original FSI uses unilateral data on exports of financial services of each jurisdiction to derive the global scale weights, i.e. the share of the value of each jurisdiction's financial services provided to foreign residents on the value of the global total of cross-border financial services. Where data is missing, the FSI extrapolates for exports of financial services from data on portfolio investment. In contrast, the bilateral version of the index requires data on the bilateral level, at which data on exports of financial services are not available. Therefore, to construct the bilateral scale weights, we use data on cross-border portfolio investment, which we source from the IMF's Coordinated Portfolio Investment Survey. For 2015, the dataset includes data on the value of cross-border portfolio assets for 14,038 bilateral relationships. The second part of the BFSI are the secrecy scores which measure the level of financial secrecy of each jurisdiction. which we source from the original FSI in its 2018 version (Cobham, Janský, and Meinzer 2015, Tax Justice Network 2018).

For automatic exchange of information, we use bilateral data available on the OECD's Automatic Exchange Portal, as updated last on 21 December 2017 (OECD 2018). This portal displays all activated relationships between pairs of jurisdictions. Notwithstanding other conditions, an exchange relationship is activated whenever two jurisdictions either conclude a bilateral competent authority agreement or list each other under the multilateral competent authority agreement (MCAA) in its Annex E (Meinzer 2017, 14). However, Annex E is not made public. This prevents us from directly observing countries' preferences for activating – or not - exchanges with any given jurisdiction. Therefore, only pairs of countries can be observed which have chosen each other in Annex E or have otherwise concluded a bilateral agreement. A further complicating factor is the absence of harmonised deadlines for the submission of countries' exchange preferences and the fact that many jurisdictions have committed to exchange only in 2018 or some even later (OECD 2017). Furthermore, the updates on the OECD data portal are made without clear timelines. Therefore, our data sample is a snapshot in time which will need to be complemented by analyses further down the line.

Three complicating factors concern the multilateral agreements. The first consists of the possibility for jurisdictions to voluntarily choose only to send, but not receive, tax information. These jurisdictions enlist in Annex A and will not be receiving any information. Moreover, the banks in any participating jurisdiction will not be required to report accounts held or controlled by people resident in those jurisdictions. The risk of this tactic clearly consists in notorious tax havens attempting to lure foreign residents into taking up fake residency or citizenship there, with tax information exchanges falsely being classified as belonging to an Annex A jurisdiction resident, which will thus not be collected nor exchanged by the banks at all (Tax Justice Network 2018, 97–104, 133–40). The second problem consists in the data protection assessments the OECD is currently performing on entrants to the automatic information exchange mechanism, the outcomes of which remain confidential. As long as the OECD diagnosed weaknesses in data protection, the jurisdiction in question would not be eligible to receive any data under competent authority agreements. There is no way to differentiate between the first and second type of asymmetric data provision (Annex A or data protection concerns). The third complicating factor is the EU directive on automatic information exchange (Council of the European Union 2014), which does not provide for non-reciprocal information exchanges and which overrides any EU member's preference as expressed in Annex A of the MCAA, and which also might override the data protection assessments of the OECD. In addition to the EU member states, there are specific treaties between the EU as a whole and six non-EU members in place which very likely only allow for reciprocal exchanges. The countries concerned are Switzerland, Liechtenstein, San Marino, Andorra, Monaco and Saint-Barthelemy (European Commission 2017a). As a result, we observe in the data that some jurisdictions (Cyprus, Romania) are exchanging information reciprocally with the EU and a handful of third countries covered by EU-equivalent treaties, but not with the rest of the world. While it is impossible for us to know the reasons for sure, it is likely that data protection concerns explain Romania's exclusion, and Annex A might explain Cyprus' asymmetry.

The last group of data we use in our empirical analysis are blacklists of tax havens published by the EU. On December 5, 2017, after years of political pressures and negotiations, the European Commission published a blacklist of 17 non-cooperative jurisdictions (European Commission 2017). The blacklist, which we will call

Blacklist A in the remainder of this paper, is a result of a screening process that has covered 92 jurisdictions. 72 of these were asked to address deficiencies, and 47 of them committed to “improve transparency, stop harmful tax practices, introduce substance requirements or implement OECD BEPS.” (European Commission 2017). Eight countries were given more time to address the deficiencies because they were recently hit by natural disasters. Finally, the remaining 17 jurisdictions were blacklisted as non-cooperative. On January 23, 2018, the European Commission reduced the 17-country list to 9 following additional commitments from 8 countries. The second blacklist we use to compare the results of the BFSI with, Blacklist B, is the 47-member list of jurisdictions that have committed to improve cooperation with the EU tax authorities. The third blacklist we analyse is a 30-country list dubbed the pan-EU list, which was created by consolidating individual member states’ blacklists. Jurisdictions were included in the final list if they were mentioned at least 10 times. We will call this list Blacklist C.

3 Methodology

In this section we describe our methodology used to estimate, first, for each country which secrecy jurisdictions harm them most and, second, whether countries are successful in targeting these jurisdictions with their policies. To do so, we build on existing approaches to monitoring financial secrecy and its impact, most notably the FSI (Cobham, Janský, and Meinzer 2015). Whereas the FSI is designed to identify the most important secrecy jurisdictions globally, the BFSI aims to identify secrecy jurisdictions for specific countries, bilaterally. Since the FSI is a well-established indicator in both policy and academic discourse (Cobham, Janský, and Meinzer 2015), we aim to maintain consistency between the FSI and the BFSI to as great an extent as possible.

The FSI is composed of two parts – secrecy scores (SS) and global scale weights (GSW). The secrecy scores reflect the extent to which jurisdictions are secretive and may range from 0 (least secretive) to 100 (most secretive). The secrecy score values used are from the FSI in its 2018 edition and are based on 20 explicit, detailed, verifiable and equally weighted indicators that measure the secrecy provided to non-residents in the laws and regulations of each jurisdiction. The 20 indicators are grouped around four broad dimensions of secrecy: (1) ownership registration (five indicators); (2) legal entity transparency (five indicators); (3) integrity of tax and financial regulation (six indicators); and (4) international standards and cooperation (four indicators). A detailed description of the secrecy scores and each of its indicators is provided by Tax Justice Network (2018). The second part of the FSI, the GSW, measure each jurisdiction’s share on the total global value of exports of financial services. This variable is used as a proxy for the relative importance of the scale of a jurisdiction and is complemented by data extrapolated from other sources following IMF’s methodology (Zoromé 2007) to estimate the GSW for 2015 data. The two entities, the SS and the GSW, are then combined using a cube/cube-root formula to derive the Financial Secrecy Index.² This formula is used to measure each jurisdiction’s contribution to global financial secrecy in a way that highlights harmful secrecy regulations.

In the construction of the BFSI, we follow the FSI’s methodology as closely as possible to maintain consistency. The BFSI uses the same information for secrecy scores as published in the 2018 version of the FSI, but it applies a bilateral scale weight (BSW) specific for each country instead of the GSW. Because the data on exports of financial services used for the original GSW is not available in bilateral country-level breakdown, we are using IMF’s 2015 data on total portfolio investment as an approximation for financial services exports.³ The BSW thus estimates the share of each country’s total portfolio investment with a jurisdiction as a ratio to the total global cross-border portfolio investment.

In line with the GSW, we define the BSW as:

$$BSW_{ij} = \frac{\text{Cross – border portfolio assets (true or approximated)}_{ij}}{\text{Sum of all global cross – border portfolio assets (true or approximated)}}$$

for each jurisdiction i and each country j . We then define the BFSI, using secrecy scores from the 2018 FSI and the same transformation as in the FSI, as:

$$\text{Bilateral Financial Secrecy Index}_{ij} = \text{Secrecy Score}_i^3 * \sqrt[3]{\text{Bilateral Scale Weight}_{ij}}$$

and thereby we obtain one BFSI for each country j with values for partner jurisdictions i .

² As explained by Cobham et al. (2015), since there is significantly more variation in the scale weighting than the secrecy score, they transform the two to generate a series with variations of a similar order. The simplest transformations that achieve this are to take the cube of the secrecy score and the cube root of the scale weight. See also Tax Justice Network (2018) for more information on the choice of the combination formula and an analysis of alternative combinations.

³ We considered another opportunity for estimation of the BSW, provided by the UN, which, unlike the IMF, publishes some bilateral data on trade in financial services. However, the number of observations in the UN dataset is very limited and we thus still strongly prefer the total portfolio investment data. We empirically explored the possibility of combining the UN information on bilateral exports of financial services and the IMF’s information on portfolio investment, but the limited availability and quality of the UN data led us to conclude that it was advisable for the time being to use only the IMF data.

As with the methodology of any policy indices, we are, of course, aware that the quality of the BFSI cannot be any better than the quality of its components and the underlying data. First, despite their imperfections, we consider the secrecy scores of the FSI the best available indicators of financial secrecy and the academic as well as policy debate seem to support this view (Clark, Lai, and Wójcik 2015). Furthermore, the approach to quantify the scale weights of the FSI is the best established methodology to determine the extent of financial secrecy, although there is an ongoing discussion on how best to combine the two components (Becker et al. 2016). Last but not least, we use the best available data, while keeping in mind their weaknesses. In particular, the IMF's portfolio investment statistics on which we rely for the construction of the BSW might not reflect well the whole scale of activities related to financial secrecy and might thus lead to imprecise results, however, the lack of alternative data sources at the bilateral level and with a wide coverage of countries prevents us from improving on these results. We propose that until further research which will likely use new data that become available only in the future fully addresses these issues, we shall interpret the results discussed in this paper with caution.

After establishing the BFSI, we address the question of whether countries are successful in targeting the most important secrecy jurisdictions by analysing two major streams of policy efforts to tame tax havens. First, we compare the results of the BFSI with three blacklists of non-cooperative jurisdictions published by the European Commission in the recent years and observe to what extent has the selection process used to compile these blacklists successfully identified the most harmful secrecy jurisdictions for the EU member states.

The second major policy effort to combat financial secrecy that we compare with the BFSI results is automatic exchange of information. In particular, we study the extent to which countries have so far covered harmful secrecy by having activated automatic exchange of information. To that end we construct the share of received (supplied) secrecy of each country as measured by the BFSI that is covered by activated AIE relationships on the sum of the country's total received (supplied) secrecy. This share for country i is thus defined as follows:

$$\text{Share of received/supplied BFSI covered by AIE}_i = \frac{\sum_{j=1}^k \text{BFSI}_{ij}}{\sum_{l=1}^m \text{BFSI}_{il}}$$

where k is the number of jurisdictions j with which country i has activated an AIE relationship, and m is the number of jurisdictions l for which the BFSI is estimated for country i .

An important caveat to consider in this part of the analysis is that the secrecy scores themselves include an indicator on automatic exchange of information. In particular, Key Financial Secrecy Indicator 18 (KFSI-18; see Tax Justice Network 2018, p. 133) focuses precisely on AIE. Since the final SS of a jurisdiction is calculated as the arithmetic average of 20 KFSI, for the purposes of this part of the analysis, we derive an alternative set of SS which exclude KFSI 18. These alternative SS are thus constructed as arithmetic averages of 19 KFSI. We do this to prevent potential endogeneity of SS when assessing the relationship between FSI and AIE.

Next, we hypothesize that secrecy jurisdictions that contribute most to global financial secrecy or that have a very high secrecy score seek to defend their business model by avoiding or at least delaying the activation of AIE relationships with countries to which they supply their secrecy (as opposed to countries that lose out due to the secrecy jurisdictions' secrecy which aim to cover as much of the received secrecy as possible by AIE). Specifically, we analyse whether countries that score high on the FSI 2018 have so far been successful in keeping the highest possible share of the secrecy they supply uncovered by AIE relationships. To do so, we estimate the following model:

$$\text{Share of supplied BFSI covered by active AIE}_i = \alpha + \beta * \text{FSI}_i + \gamma * X_i + \mu \quad (1)$$

where FSI_i is the value of the 2018 FSI of country i , X_i is a set of income and regional group binary variables, and μ an error term. We hypothesize that $\beta < 0$, i.e. that countries that score higher on the FSI manage to avoid or delay the activation of AIE relationships with countries to which they supply a lot of harmful secrecy (as measured by the BFSI). In addition, we estimate a version of this model that divides the FSI value into its two components, the secrecy scores and the global scale weights, to determine which of the two factors is driving the negative relationship.

4 Results

In this section we first present the estimated values of BFSI as a background and a starting point for the main results and its policy applications in the form of the EU’s blacklist and AIE. So, we begin the discussion of our results by presenting the results of the BFSI itself. As an illustration of what the BFSI is, we present its results for a few selected countries, because the number of countries for which we have estimated the BFSI, 86, does not enable us to present all the detailed results in this limited space.⁴ Table 1 shows the results of the BFSI for three rich countries from three continents: Germany, Japan and the United States. For each of them, it shows the top ten jurisdictions with the highest values of the BFSI. The table also shows the two components on which the BFSI is based: the secrecy score value from the FSI 2018 and the BSW. The results for the three countries show that three secrecy jurisdictions are in all three top ten sets (Switzerland, Cayman Islands, the Netherlands).⁵ Yet, we also observe that there is substantial heterogeneity and a number of one-off jurisdictions. Indeed, given this level of heterogeneity for three countries that are relatively similar in terms of their level of development and their interconnectedness, we expect even higher heterogeneity when comparing countries from different income groups and across regions. For the United States we observe that there is some overlap of its top ten secrecy jurisdictions with the six major profit havens (the Netherlands, Ireland, Bermuda, Luxembourg, Switzerland, Singapore) identified by Cobham & Janský (2015), with Switzerland, Bermuda and the Netherlands being in both groups.

Table 1. Top ten secrecy jurisdictions and BFSI results for Germany, Japan and the United States of America

Rank	Germany	SS	BSW	BFSI	Japan	SS	BSW	BFSI	United States	SS	BSW	BFSI
1	Netherlands	66.03	0.52%	498.80	Cayman Islands	72.28	1.41%	911.12	Cayman Islands	72.28	2.77%	1142.17
2	Switzerland	76.45	0.11%	460.07	United States	59.83	3.12%	673.97	Switzerland	76.45	0.95%	947.92
3	Luxembourg	58.20	1.20%	450.84	Netherlands	66.03	0.27%	400.20	Bermuda	73.05	0.49%	663.37

Having shown the BFSI for individual countries, we show how the most harmful secrecy jurisdictions vary across groups of countries. As an example, in Table 2 we explore the differences between countries grouped according to their per capita income and we provide similar results for the regional groups in the Appendix.⁶

⁴ Altogether we estimate the BFSI for 86 countries and how they are harmed by 112 secrecy jurisdictions, which – due to not having all the data for all the potential country-secrecy jurisdictions pairs - results into 4939 estimated values. We find that a relatively small number of relationships is responsible for a large share of BFSI - of the 4939 relationships for which we have estimated the BFSI, the top 50 alone are responsible for 9.46% of all global secrecy as measured by the BFSI. In Table A1 in the Appendix we provide a list of the fifteen relationships with the highest BFSI values.

⁵ Using similar logic as in Table 1, we can reverse the analysis and look at countries that supply the most secrecy to other jurisdictions by summing up the BFSI scores for jurisdictions that supply secrecy. By doing so, we essentially create a single ranking of jurisdictions in terms of how much secrecy they provide to other countries – an objective of the original FSI from which the BFSI departs by using a different variable, portfolio assets at the bilateral level, as the scale weight. The results of the summed BFSI and the original FSI are indeed quite similar, with a correlation coefficient of 0.865. It is thus no surprise that the same secrecy jurisdictions come out at the top of the ranking– the United States are followed by Cayman Islands, Switzerland, the Netherlands and Luxembourg. Table A2 in the Appendix shows the top ten receivers of secrecy from the top four suppliers of secrecy.

⁶ Furthermore, we can assess which regions provide most secrecy to other regions. We again use the classification of countries by the World Bank and find that, in line with previous evidence, there are some secrecy jurisdictions that specialize in certain regions that are geographically close to them, such as the United Arab Emirates for the Middle East and South Asia. The results for all seven regional groups are presented in Table A4 in the Appendix. We derive the matrix of shares of total global secrecy among regional groups (Table A5 as well as Figure A1 in the Appendix) and

We employ the World Bank’s classification of five income groups valid as of July 2016, but since there is no data available to estimate the BSW for any of the low-income countries, we only compare the remaining four income groups. Six jurisdictions are included among the top 10 jurisdictions for all four income groups – the United States (which top the list for every income group), Hong Kong, the Netherlands, the Cayman Islands, Switzerland and United Arab Emirates. These results suggest that the major global financial centres are responsible for most of the secrecy received by most countries, regardless of their income. Still, there are secrecy jurisdictions such as Luxembourg or Bermuda that seem important only for some groups of countries.

Table 2: Top ten secrecy jurisdictions for four income groups

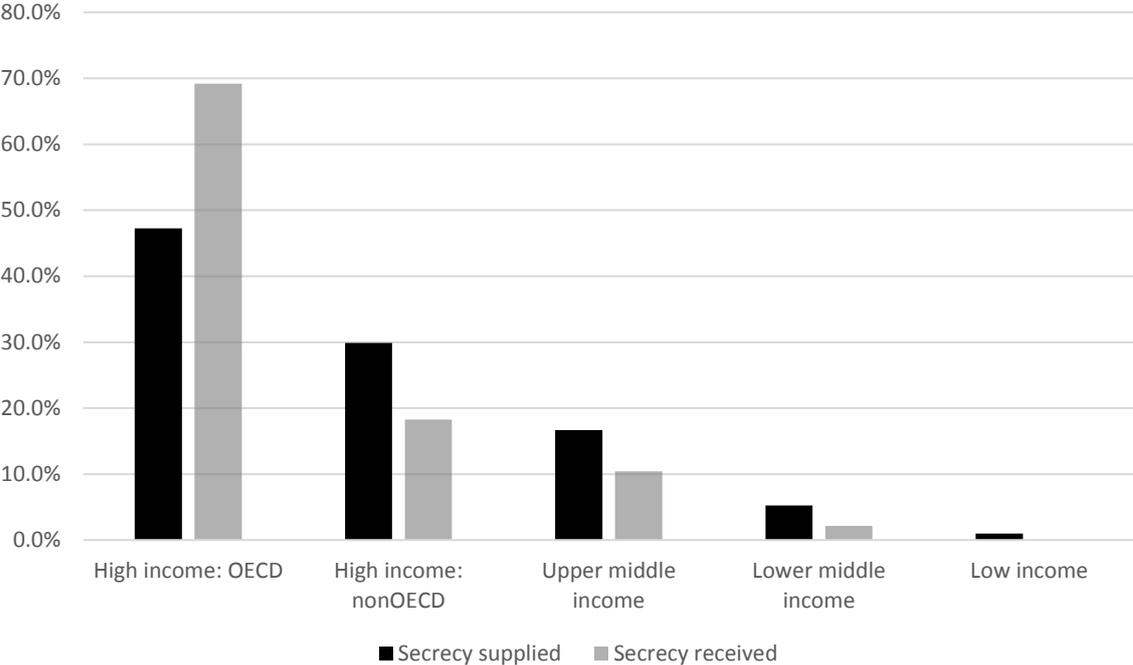

Rank	Lower middle income	BFSI	Upper middle income	BFSI	High income: nonOECD	BFSI	High income: OECD	BFSI
1	United States	435.93	United States	2170.79	United States	3263.12	United States	8448.78
2	Cayman Islands	335.36	Cayman Islands	1345.38	Cayman Islands	2646.67	Switzerland	7758.41
3	Netherlands	318.23	Hong Kong	1202.20	United Arab Emirates	1752.42	Cayman Islands	7594.26
4	Hong Kong	298.27	Switzerland	1072.61	Bermuda	1654.66	Netherlands	7080.64
5	United Arab Emirates	285.56	Luxembourg	961.18	Switzerland	1642.51	Luxembourg	6035.72
6	Switzerland	215.33	Netherlands	853.25	Luxembourg	1465.38	Germany	5700.51
7	China	203.93	Bermuda	808.00	Hong Kong	1439.24	Japan	4357.19
8	Malaysia	184.28	Singapore	805.13	China	1434.94	Hong Kong	4341.20
9	Saudi Arabia	179.06	United Arab Emirates	782.44	British Virgin Islands	1425.70	Taiwan	4013.14
10	Germany	175.42	Germany	748.51	Netherlands	1399.01	United Arab Emirates	3964.31

In addition to grouping the receivers of secrecy, we can also group the suppliers of secrecy and thus analyse the relationships among the groups. Figure 1 pictures the shares of global secrecy supplied and received by each income group. In total, OECD countries receive 69% of the global secrecy, while only supplying 47%. The results suggest that the remaining income groups supply more secrecy that they receive. Similarly, Table A3 in the Appendix shows a matrix of shares of secrecy supplied by income groups in columns to income groups in the rows, in which we observe that high income countries from the OECD supply 34% of total global secrecy to other OECD countries.

find that Europe & Central Asia supplies 40% and receives 54% of the total global secrecy, most of which is among the members of this geographical group. We also find that while Europe & Central Asia and North America are among the regions that receive more secrecy than they supply, Latin America & the Caribbean and East Asia & Pacific supply this additional secrecy.

Figure 1: Shares of global secrecy supplied and received by each income group

Source: Authors.

The BFSI also allows to easily derive a ranking for specific political groups, such as the European Union, and thus provides a useful tool to analyse which countries are potentially most harmful for EU member states. We compare the results of a common BFSI for EU member states with jurisdictions that the European Commission included on its three blacklists of non-cooperative jurisdictions (as described in Section 2).⁷ First, we consider the list of 17 jurisdictions which was published in December 2017 and later reduced in January 2018 to 9 jurisdictions following commitments of 8 jurisdictions to amend regulations in the near future (Blacklist A). Secrecy scores are available for 11 of these jurisdictions, which together account for mere 9.74% of the secrecy faced by the EU member states from jurisdictions outside the EU. Of the top fifteen most harmful secrecy jurisdictions according to the BFSI, only the United Arab Emirates were included on the blacklist, and they were removed in January 2018.

Second, we analyse the list of 47 jurisdictions – which we call Blacklist B – that fitted the pre-set criteria used to create Blacklist A, but have managed to stay off Blacklist A thanks to their prior commitment to amend regulation. Secrecy scores are available for 28 of these jurisdictions, which are altogether responsible for 26.7% of the secrecy received by EU member states. We find nevertheless that ten of the top fifteen BFSI jurisdictions are included on Blacklist B, with only the United States, Japan, British Virgin Islands, and Canada missing, and the United Arab Emirates having moved from Blacklist A to Blacklist B only recently.

⁷ By European Commission’s design, all three blacklists automatically omit EU member countries, while the BFSI can be used to quantify the extent to which EU countries harm other EU member states relative to jurisdictions outside the EU. We find that according to the BFSI, 35% of the secrecy faced by EU countries is supplied by other member states (most importantly by the Netherlands and Luxembourg). This result should be interpreted with a bit of caution. The secrecy scores as measured by the FSI are marginally lower among the EU member states than to of EU members states towards the outer world because among EU members international cooperation is more intense and thus some indicators (mainly 18, 19, and 20) would score often more transparent (but not always – e.g. Austria on indicator 18 on automatic information exchange). Separately, another useful observation can be made from the results of the BFSI if we focus on one particular group of jurisdictions that is often pointed to as harmful to the financial transparency in the EU – the British Overseas Territories and British Crown Dependencies. This group includes some of the most prominent secrecy jurisdictions in the world, including the Cayman Islands, Bermuda or Guernsey. We find that of the total secrecy received by the EU member states from the outside world, the British Overseas Territories are responsible for 11% and the British Crown Dependencies for 6%.

In other words, while the EU has to a large extent succeeded to identify the most potentially harmful jurisdictions according to the BFSI, none of these have made it to the most recent list from January 2018 due to their promise to cooperate in the near future. Third, we consider an earlier list of 30 jurisdictions that have appeared on at least 10 blacklists compiled by each EU member state. Six jurisdictions of the top fifteen have appeared on this blacklist, which we call Blacklist C. Table 3 present an overview of the results of a common BFSI for EU28 countries, including these jurisdictions' secrecy scores and information on whether the EU's blacklists of non-cooperative jurisdictions include the jurisdiction.

Table 3: Top 15 secrecy jurisdictions for EU member states and three EU blacklists

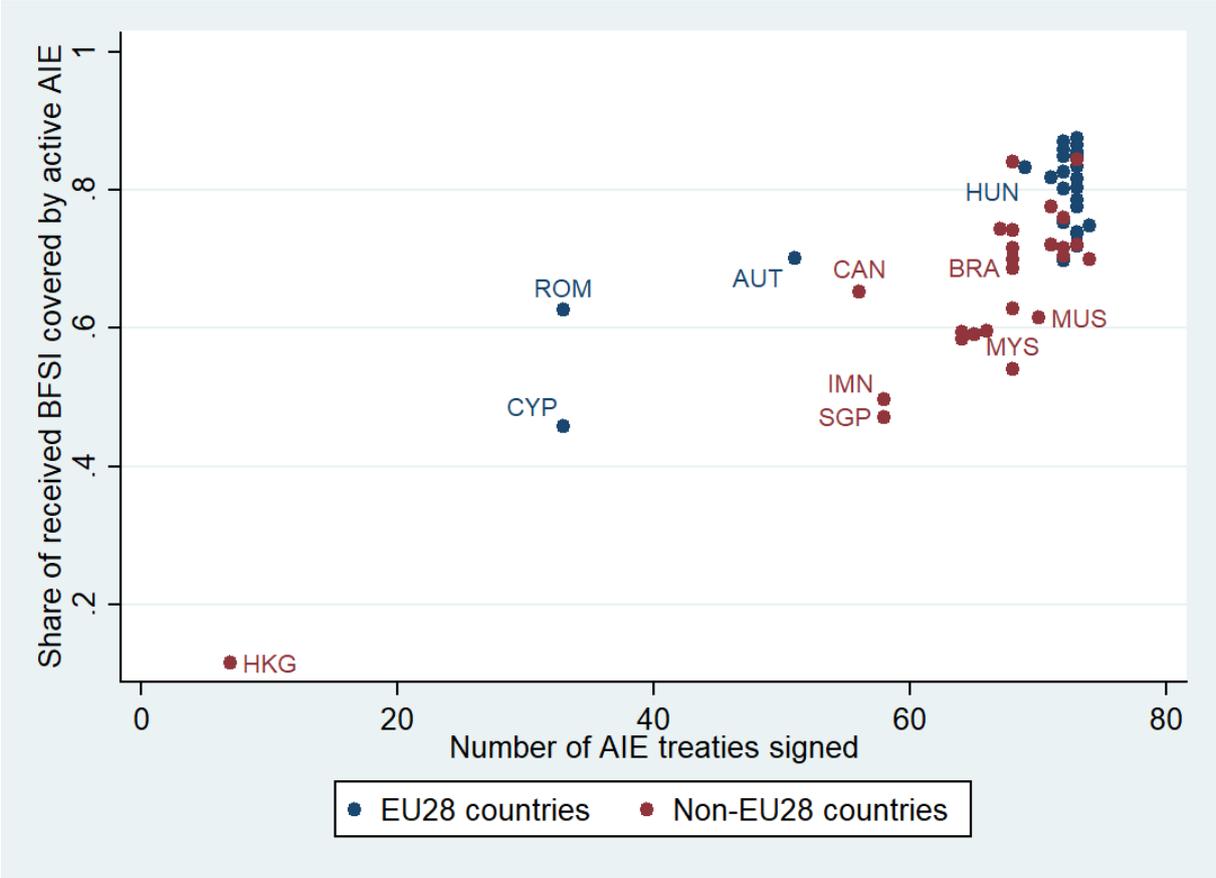

Rank	Country	BFSI value	Secrecy score	Blacklist A	Blacklist B	Blacklist C
1	United States	5519.55	59.83	0	0	0
2	Switzerland	5043.08	76.45	0	1	0
3	Cayman Islands	4013.83	72.28	0	1	1
4	Japan	2661.46	60.50	0	0	0
5	United Arab Emirates	2503.45	83.85	1*	0	0
6	Hong Kong	2455.64	71.05	0	1	1
7	Turkey	2350.30	67.98	0	1	0
8	Bermuda	2317.49	73.05	0	1	1
9	Jersey	2222.51	65.45	0	1	0
10	Taiwan	2205.95	75.75	0	1	0
11	Guernsey	2202.64	72.45	0	1	1
12	Thailand	1930.65	79.88	0	1	0
13	British Virgin Islands	1733.57	68.65	0	0	1
14	Canada	1724.34	54.75	0	0	0
15	Curacao	1679.54	74.80	0	1	0

Note: A star indicates that the country has been removed from the published blacklist following its promise to commit to improvement.

We now turn to testing whether countries, in their efforts to counter tax havens, focus on the most important secrecy jurisdictions. In particular, we focus on one specific channel through which countries aim to lower financial secrecy - automatic exchange of information (AIE). As described above, we calculate the share of the values of the BFSI for relationships with jurisdictions with which a country has an activated AIE relationship on the total sum of the country's BFSI. We report these results only for countries for which we estimated the BFSI for at least 10 jurisdictions. In total, the BFSI is estimated for 86 countries, of which 81 have the BFSI estimated for at least 10 jurisdictions. Figure 2 shows the share of BFSI accounted for by countries which are covered by an existing activated AIE treaty versus the number of AIE relationships set up with these jurisdictions. We observe that while some countries have been quite successful in covering up to 85% of the financial secrecy received, for others, this share is around 60% even though some of these countries already activated more than 60 AIE relationships.

Figure 2: Share of BFSI covered by currently activated AIE relationships vs. the number of activated AIE relationships

Source: Authors.

This straightforward comparison between a share of financial secrecy covered by AIE and the number of AIE treaties signed can help us identify cases in which the attention and resources of policymakers regarding AIE might not be directed to the jurisdictions which harm their countries the most. For example, Brazil, while having activated 68 AIE relationships, has covered only 68.65% of its total BFSI. In particular, Brazil does not have a treaty on AIE with 7 out of its top ten largest contributors to harmful financial secrecy. As Brazil is not generally regarded as a secrecy jurisdiction (it ranked 73rd out of 112 on the FSI 2018 with a secrecy score of 49, one of the lowest in the world), its low share of BFSI covered by AIE treaties despite a large number of activated relationships may be interpreted as misaimed efforts of its policymakers. Incidentally, Brazil has also been identified by Janský and Palanský (2017) as one of the countries that lose the most tax revenue as relative to their GDP due to corporate profit shifting related to foreign direct investment. In contrast, New Zealand has activated the same number of AIE relationships as Brazil, and in doing so has covered 85.7% of the secrecy it receives. Malaysia and China are in a similar situation. We argue that the BFSI may be a useful tool for such countries when deciding about where to focus their policymakers’ efforts next.

We expect that many secrecy jurisdictions would aim not to have signed AIE with countries important for them. Hong Kong is a clear example of a secrecy jurisdiction that provides substantial secrecy to other jurisdictions and yet has activated only very few AIE relationships so far. One particular country that does not yet participate in AIE and is, at the same time, responsible for a significant share of received secrecy in a number of countries, is the United States. For example, Mexico has activated 56 treaties on AIE and has thus covered 73.9% of the BFSI that it faces. Adding an AIE relationship with the US would increase the coverage by 8.9 percentage points. Instead of joining the bulk of countries that have signed the AIE treaties, the US has implemented its own standard, FATCA, which, however, is not a bilateral treaty on two-way

exchange of information, but rather a rule granting the US a non-reciprocated access to information about foreign persons (Knobel 2016).

Furthermore, in Figure 2, we see that four EU member states have a particularly low number of activated AIE relationships – Cyprus, Romania, Austria and Hungary. It is not a coincidence that some of these countries, along with Luxembourg, Ireland and the Netherlands, are often considered as tax havens. Austria delayed the introduction of automatic information exchange for many decades, whilst providing high secrecy to account holders and being a popular destination for German capital (Tax Justice Network 2018a), while Hungary publicly proclaims their efforts to lure in foreign capital by offering the lowest corporate tax rate in Europe within the EU28 countries (Reuters 2018).

Figure 3 shows the relationship between the share of supplied secrecy covered by activated AIE treaties and the FSI value of all 66 countries in the sample for which Secrecy Scores are available and which have the BFSI estimated for at least 10 jurisdictions. We observe that the relationship is negative, suggesting that jurisdictions that score highly on the FSI are less likely to activate AIE relationships with countries that are significant destinations for their secrecy. In addition to this trend, there is a cluster of jurisdictions in the bottom left corner of the graph that have low FSI values and, at the same time, have not yet disclosed any AIE exchange partners. We recognize three possible explanations. First, these jurisdictions aim to gain from their secrecy by attracting wealth from abroad, and so far they have been successful in avoiding the activation of any AIE relationships (either by delaying the start of the signed treaties or by not signing any treaties). Second, these jurisdictions' foreign activities may be very small and it is thus not on their policymakers' agendas to negotiate AIE treaties at all. Third, if the jurisdiction's foreign activities are indeed very small, it may be the case that it is not on the agenda of policymakers of other countries to negotiate AIE relationships with these jurisdictions. There is a theoretically possible fourth explanation – that some of these countries have activated some AIE relationships, but there is no data available on portfolio assets between these countries, which is why the share of covered BFSI would be zero. However, there is no such case.

Table 4: Estimation of the relationship between FSI value and the share of supplied BFSI covered by AIE treaties

	(1)	(2)	(3)	(4)
FSI2018	-.000117** (.0000581)	-.000155* (.0000859)	-.00012* (.0000594)	-.00016** (.0000728)
Regional groups	Yes	No	Yes	No

Note: Robust standard errors in parentheses. *** $p < 0.01$, ** $p < 0.05$, * $p < 0.1$.

To further examine the relationship and to provide more insight into which secrecy jurisdictions manage to keep out of the AIE system entirely, we divide the explanatory variable into its components: the secrecy scores and the global scale weights. In doing so, we assess whether the negative relationship found above is driven by secrecy or by the scale of cross-border activity. Figure 4 shows the relationship between secrecy scores and the share of supplied BFSI covered by AIE. We observe that only countries with relatively high secrecy (with Secrecy Scores above 58) have not yet activated any AIE relationships, which is a result in favour of our first explanation for no AIE relationships – that there are jurisdictions that aim to gain from their secrecy by attracting wealth from abroad, and so far they have been successful in avoiding activating any AIE relationships.

Figure 4: Relationship between the share of supplied BFSI covered by AIE treaties and secrecy scores

Source: Authors.

In Table 5 we present the results of the estimation of a similar model that was represented by Equation 1, with secrecy scores and global scale weights as explanatory variables instead of the FSI value. We find that both the secrecy scores and the global scale weights are negatively associated with the share of supplied BFSI covered by AIE treaties. The results suggest that higher secrecy and higher cross-border provision of financial services are both indicators of a tendency of jurisdictions to delay the activation of less important AIE relationships.

5 Conclusion

In the wake of the Panama Papers both academic research on the role of secrecy jurisdictions and policy responses to their harmful financial secrecy have intensified. Recent research findings evaluate the effects of offshore leaks on the valuation of firms or draw on the data leaked by the Panama Papers to shed more light on income inequality hidden by secrecy jurisdictions. The European Parliament's Committee of Inquiry into Money Laundering, Tax Evasion and Tax Avoidance (aka "PANA") has issued far reaching policy recommendations in late 2017, and the Panama Papers have arguably contributed to a December 2017 European Union anti-money laundering directive that includes a requirement for companies to disclose their beneficial owners in a publicly available register. Yet, no academic research has so far provided evidence for more targeted policy responses through the identification of the most important secrecy jurisdiction for every country worldwide. This is a task that we set for ourselves in this paper.

Indeed, in this paper we argued that individual tax havens affect countries to a varying extent. To answer which jurisdiction's financial secrecy is harmful to which countries, we built on the existing Financial Secrecy Index and developed its country-specific extension, the Bilateral Financial Secrecy Index. For 86 countries we created rankings of up to 112 secrecy jurisdictions they receive financial secrecy from. Its results pointed to major offshore financial centres being responsible for the bulk of global financial secrecy, but with substantial heterogeneity in the specific countries that secrecy jurisdictions cater to. We found that, for example, the Netherlands and Luxembourg are among the most harmful secrecy jurisdictions in the European Union; that Mauritius specializes in providing secrecy to countries in South Asia and Africa; or that the United States, Switzerland and the Cayman Islands are important secrecy jurisdictions for most countries in the world.

Importantly, we explored how the BFSI can be useful for policymakers in determining on which secrecy jurisdictions they should focus their limited resources on. We find that the December 2017 European Commission's list includes only 11 out of 15 secrecy jurisdictions that are most harmful for the European Union. In addition, we analysed one of the recently launched areas of cooperation – automatic information exchange. We find that many countries worldwide are not successful in establishing automatic exchange of information with their most important secrecy jurisdictions. We also find that jurisdictions that score highly on the FSI have so far been successful in avoiding the activation of AIE relationships with the countries to which they provide significant amounts of secrecy.

Our results unveil a new geography of financial secrecy, one in which major global financial centres play first fiddle and in which some tax havens strategically target specific countries. Our paper also contributes to the relatively scarce research on how different tax havens affect different countries, while future research should consider specific areas of financial secrecy, related to trade, banking, or investment. Our methodology and results provide insights for both specific countries and groups of countries and it thus also paves the way for additional research, for example, in the area of the political economy of financial secrecy and related policy actions. Last, but not least, since countries are still being harmed by a variety of secrecy jurisdictions, Panama or others, more targeted policy efforts can diminish financial secrecy and thus the harm done. In this respect, we believe that the BFSI may provide useful guidance to policymakers around the world in their efforts to diminish the harmful role of secrecy jurisdictions.

Table A1: The most potentially harmful relationships

Supplier of secrecy	Receiver of secrecy	Secrecy score	Bilateral scale weight	BFSI value
Cayman Islands	United States	72.28	2.77%	1142.17
Switzerland	United States	76.45	0.95%	947.92
Cayman Islands	Japan	72.28	1.41%	911.12
Cayman Islands	Hong Kong	72.28	0.73%	732.09
United States	Japan	59.83	3.12%	673.97
Bermuda	United States	73.05	0.49%	663.37
United States	Cayman Islands	59.83	2.60%	634.08
Netherlands	United States	66.03	0.92%	602.96
United States	United Kingdom	59.83	2.20%	600.19
Bermuda	Hong Kong	73.05	0.35%	590.36
Taiwan	United States	75.75	0.25%	585.97
Japan	United States	60.50	1.85%	585.18
United States	Luxembourg	59.83	2.02%	583.00
Switzerland	Luxembourg	76.45	0.20%	565.54
Switzerland	United Kingdom	76.45	0.19%	557.75

Table A3: Shares of secrecy supplied by income groups in the columns to income groups in the rows

	High income: OECD	High income: nonOECD	Upper middle income	Lower middle income	Low income	Total
High income: OECD	34.0%	19.3%	11.4%	3.6%	0.8%	69.2%
High income: nonOECD	7.7%	6.3%	3.3%	0.9%	0.1%	18.2%
Upper middle income	4.6%	3.6%	1.6%	0.5%	0.1%	10.4%
Lower middle income	0.9%	0.7%	0.4%	0.1%	0.0%	2.1%
Low income	0.0%	0.0%	0.0%	0.0%	0.0%	0.0%
Total	47.3%	29.9%	16.7%	5.2%	1.0%	100.0%

Source: Authors.

Table A4: Top ten most potentially harmful secrecy jurisdictions for seven regional groups

Rank	East Asia & Pacific	Europe & Central Asia	Latin America & Caribbean	Middle East & North Africa	North America	South Asia	Sub-Saharan Africa
1	Cayman Islands	United States	United States	United Arab Emirates	Cayman Islands	United Arab Emirates	United States
2	United States	Netherlands	Cayman Islands	United States	Switzerland	United States	Bermuda
3	Hong Kong	Switzerland	Switzerland	Switzerland	Netherlands	Saudi Arabia	Hong Kong
4	China	Luxembourg	Luxembourg	Turkey	Japan	Hong Kong	Singapore
5	Bermuda	Cayman Islands	Netherlands	Cayman Islands	United States	Turkey	India
6	Switzerland	Germany	Panama	Bahrain	Hong Kong	China	Luxembourg
7	Netherlands	Japan	British Virgin Islands	Netherlands	Taiwan	Cayman Islands	Cayman Islands
8	Thailand	France	Germany	Germany	Bermuda	Thailand	Switzerland
9	Taiwan	United Arab Emirates	Bermuda	Malaysia	Germany	Switzerland	Kenya
10	Singapore	Hong Kong	Japan	Hong Kong	Thailand	Malaysia	Guernsey
